

1    **ABSTRACT OF THE DISCLOSURE**

2            A recovery force adjusting device for a cymbal stand includes a handle, a  
3    driving ring movable relative to the column and having a pin extending through the stop,  
4    a supporting seat having a cutout and a wedge the supporting seat, a rotating sleeve  
5    rotatably and movably sandwiched between the supporting seat and the driving seat and  
6    having a first, a second and a third sets of teeth formed on the rotating sleeve and a  
7    recovery spring to move the rotating sleeve upward. Due to the misalignment  
8    relationship between the wedge and the tooth of the first set of teeth, sliding movement  
9    of the wedge along a slope of the corresponding tooth of the first set of teeth forces the  
10   rotating sleeve to rotate and thus the position of the driving ring is changed. A  
11   compression force to the spring is thus adjusted.
